Fourier Transforms: Discrete, Fast, and Practical PHYS 250 (Autumn 2019) – Lecture 14

David Miller

Department of Physics and the Enrico Fermi Institute University of Chicago

November 20, 2019

Outline

- Reminders
 - Reminders from Lecture 13

- DFT to FFT
 - Reminders of the DFT
 - Cooley-Tukey algorithm
 - Butterfly calculations
 - Danielson-Lanczos Lemma

Reminders from last time

We left off discussing details of our discrete Fourier transform and how we might speed it up.

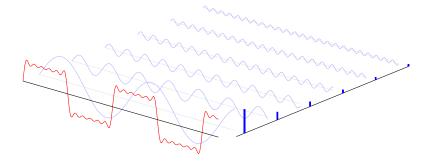

PDEs and Fourier Series

- Fourier Series → Fourier Transforms
 - We discussed how we can move to a continuous function definition of the expansion over a basis of functions
 - We then broke this down into discrete steps and obtained the Discrete Fourier Transform
- Issues encountered:
 - We realized that there is an issue related to the finite sampling of a function: aliasing
 - Began to break down the Fourier transform even further for a fast implementation

Today we will discuss the evolution towards the **FFT**, some of the practical limitations, and specific real-world (scientific and otherwise!) examples of using FFT's!

Square wave Fourier series

We already saw how we can break down a "simple" function into its components:

So let's figure out how to use this to its full capacity!

Reminders of the Discrete Fourier Transform (DFT)

We determined the form of the **DFT** last time:

$$\hat{f}(\omega) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(t)e^{-i\omega t} dt \qquad \xrightarrow{DFT} \qquad \hat{f}_n = \frac{1}{\sqrt{2\pi}} \sum_{k=1}^{N} f_k e^{-2\pi i k n/N}$$
 (1)

$$f(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} \hat{f}(\omega) e^{i\omega t} d\omega \quad \xrightarrow{DFT} \quad f_k = \frac{\sqrt{2\pi}}{N} \sum_{n=1}^{N} \hat{f}_n e^{-i\omega_n t}$$
 (2)

This has certain drawbacks which we will discuss shortly, but it also has huge advantages. Namely, we can re-write this to see some amazing computational properties.

$$\hat{f}_n = \frac{1}{\sqrt{2\pi}} \sum_{i=1}^{N} Z_N^{nk} f_k \qquad (Z_N = e^{-2\pi i/N})$$
 (3)

$$f_k = \frac{\sqrt{2\pi}}{N} \sum_{N=1}^{N} Z_N^{-nk} \hat{f}_n \qquad (n = 0, 1, \dots, N)$$
 (4)

As we mentioned last time, with this formulation, the computer needs to compute only powers of $Z \to Z_N^{nk}$.

What does this buy us, though???

As we mentioned last time, with this formulation, the computer needs to compute only powers of $Z \to Z_N^{nk}$.

What does this buy us, though???

Well, evaluating Eqs. 3–4 definition directly requires $\mathcal{O}(N^2)$ operations: there are N outputs f_k , and each output requires a sum of N terms.

As we mentioned last time, with this formulation, the computer needs to compute only powers of $Z \to Z_N^{nk}$.

What does this buy us, though???

Well, evaluating Eqs. 3–4 definition directly requires $\mathcal{O}(N^2)$ operations: there are N outputs f_k , and each output requires a sum of N terms.

What if we can make this scales as $N \ln N$???

As we mentioned last time, with this formulation, the computer needs to compute only powers of $Z \to Z_N^{nk}$.

What does this buy us, though???

Well, evaluating Eqs. 3–4 definition directly requires $\mathcal{O}(N^2)$ operations: there are N outputs f_k , and each output requires a sum of N terms.

What if we can make this scales as $N \ln N$???

This may not seem like much of a difference, for $N = 10^{2-3}$, the difference of 10^{3-5} is the difference between a minute and a week.

This is what the FFT buys us!

Let's start with the simplified form of the DFT:

$$\hat{f}_n = \frac{1}{\sqrt{2\pi}} \sum_{k=1}^N f_k e^{-2\pi i k n/N} = \frac{1}{\sqrt{2\pi}} \sum_{k=1}^N f_k Z_N^{nk}$$
 (5)

- There are imaginary components
 - Even if the signal elements f, to be transformed are real, Z_k is always complex, and therefore we must process both real and imaginary parts when computing transforms.
- We have to add and/or multiply N² times unless we break this down further
 - 3. Both m and k range over N integer values, the (Zⁿ_N)^kf_k multiplications and additions of complex numbers

Let's start with the simplified form of the DFT:

$$\hat{f}_n = \frac{1}{\sqrt{2\pi}} \sum_{k=1}^N f_k e^{-2\pi i k n/N} = \frac{1}{\sqrt{2\pi}} \sum_{k=1}^N f_k Z_N^{nk}$$
 (5)

- There are imaginary components
 - complex, and therefore we must process both real and imaginary partially when computing transforms.
 - We have to add and/or multiply N² times unless we break this down further
 - » Both a and k range over N integer values, the $(Z_0^n)^k h$ multiplications

Let's start with the simplified form of the DFT:

$$\hat{f}_n = \frac{1}{\sqrt{2\pi}} \sum_{k=1}^N f_k e^{-2\pi i k n/N} = \frac{1}{\sqrt{2\pi}} \sum_{k=1}^N f_k Z_N^{nk}$$
 (5)

- There are **imaginary components**
 - Even if the signal elements f_k to be transformed are real, Z_N is always complex, and therefore we must process both real and imaginary parts when computing transforms.
- We have to add and/or multiply N^2 times unless we break this down further
 - Both n and k range over N integer values, the $(Z_N^n)^k f_k$ multiplications require N^2 multiplications and additions of complex numbers.

The time savings comes from taking advantage of **periodicity**.

The values of the **computationally expensive complex factor** $Z^{nk} = ((Z)^n)^k$ **are repeated** as the integers n and k vary sequentially.

The time savings comes from taking advantage of **periodicity**.

$$\hat{f}^{0} = Z^{0}f_{0} + Z^{0}f_{1} + Z^{0}f_{2} + Z^{0}f_{3} + Z^{0}f_{4} + Z^{0}f_{5} + Z^{0}f_{6} + Z^{0}f_{7}$$

$$\hat{f}^{1} = Z^{0}f_{0} + Z^{1}f_{1} + Z^{2}f_{2} + Z^{3}f_{3} + Z^{4}f_{4} + Z^{5}f_{5} + Z^{6}f_{6} + Z^{7}f_{7}$$

$$\hat{f}^{2} = Z^{0}f_{0} + Z^{2}f_{1} + Z^{4}f_{2} + Z^{6}f_{3} + Z^{8}f_{4} + Z^{10}f_{5} + Z^{12}f_{6} + Z^{14}f_{7}$$

$$\hat{f}^{3} = Z^{0}f_{0} + Z^{3}f_{1} + Z^{6}f_{2} + Z^{9}f_{3} + Z^{12}f_{4} + Z^{15}f_{5} + Z^{18}f_{6} + Z^{21}f_{7}$$

$$\hat{f}^{4} = Z^{0}f_{0} + Z^{4}f_{1} + Z^{8}f_{2} + Z^{12}f_{3} + Z^{16}f_{4} + Z^{20}f_{5} + Z^{24}f_{6} + Z^{28}f_{7}$$

$$\hat{f}^{5} = Z^{0}f_{0} + Z^{5}f_{1} + Z^{10}f_{2} + Z^{15}f_{3} + Z^{20}f_{4} + Z^{25}f_{5} + Z^{30}f_{6} + Z^{35}f_{7}$$

$$\hat{f}^{6} = Z^{0}f_{0} + Z^{6}f_{1} + Z^{12}f_{2} + Z^{18}f_{3} + Z^{24}f_{4} + Z^{30}f_{5} + Z^{36}f_{6} + Z^{42}f_{7}$$

$$\hat{f}^{7} = Z^{0}f_{0} + Z^{7}f_{1} + Z^{14}f_{2} + Z^{21}f_{3} + Z^{28}f_{4} + Z^{35}f_{5} + Z^{42}f_{6} + Z^{49}f_{7}$$

There are actually only 4 independent values! Z^0, Z^1, Z^2, Z^3

$$Z^{0} = \exp(0) = +1, \qquad Z^{1} = \exp(-\frac{2\pi}{8}i) = +\frac{\sqrt{2}}{2} - i\frac{\sqrt{2}}{2}$$

$$Z^{2} = \exp(-\frac{2\pi}{8}2i) = -i, \qquad Z^{3} = \exp(-\frac{2\pi}{8}3i) = -\frac{\sqrt{2}}{2} - i\frac{\sqrt{2}}{2}$$

$$Z^{4} = \exp(-\frac{2\pi}{8}4i) = -Z^{0}, \qquad Z^{5} = \exp(-\frac{2\pi}{8}5i) = -Z^{1}$$

$$Z^{6} = \exp(-\frac{2\pi}{8}6i) = -Z^{2}, \qquad Z^{7} = \exp(-\frac{2\pi}{8}7i) = -Z^{3}$$

$$Z^{8} = \exp(-\frac{2\pi}{8}8i) = +Z^{0}, \qquad Z^{9} = \exp(-\frac{2\pi}{8}9i) = +Z^{1}$$

$$Z^{10} = \exp(-\frac{2\pi}{8}10i) = +Z^{2}, \qquad Z^{11} = \exp(-\frac{2\pi}{8}11i) = +Z^{3}$$

$$Z^{12} = \exp(-\frac{2\pi}{8}11i) = -Z^{0}, \qquad \cdots$$

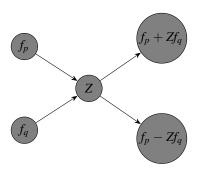

We can now put these equations in an appropriate form for computing by regrouping the terms into sums and differences of the f's:

$$\hat{f}^{0} = Z^{0}(f_{0} + f_{4}) + Z^{0}(f_{1} + f_{5}) + Z^{0}(f_{2} + f_{6}) + Z^{0}(f_{3} + f_{7})
\hat{f}^{1} = Z^{0}(f_{0} - f_{4}) + Z^{1}(f_{1} - f_{5}) + Z^{2}(f_{2} - f_{6}) + Z^{3}(f_{3} - f_{7})
\hat{f}^{2} = Z^{0}(f_{0} + f_{4}) + Z^{2}(f_{1} + f_{5}) - Z^{0}(f_{2} + f_{6}) - Z^{2}(f_{3} + f_{7})
\hat{f}^{3} = Z^{0}(f_{0} - f_{4}) + Z^{3}(f_{1} - f_{5}) - Z^{2}(f_{2} - f_{6}) + Z^{1}(f_{3} - f_{7})
\hat{f}^{4} = Z^{0}(f_{0} + f_{4}) - Z^{0}(f_{1} + f_{5}) + Z^{0}(f_{2} + f_{6}) - Z^{0}(f_{3} + f_{7})
\hat{f}^{5} = Z^{0}(f_{0} - f_{4}) - Z^{1}(f_{1} - f_{5}) + Z^{2}(f_{2} - f_{6}) - Z^{3}(f_{3} - f_{7})
\hat{f}^{6} = Z^{0}(f_{0} + f_{4}) - Z^{2}(f_{1} + f_{5}) - Z^{0}(f_{2} + f_{6}) + Z^{2}(f_{3} + f_{7})
\hat{f}^{7} = Z^{0}(f_{0} - f_{4}) - Z^{3}(f_{1} - f_{5}) - Z^{2}(f_{2} - f_{6}) - Z^{1}(f_{3} - f_{7})
\hat{f}^{8} = \hat{f}^{0}.$$
(6)

Butterfly calculations (I)

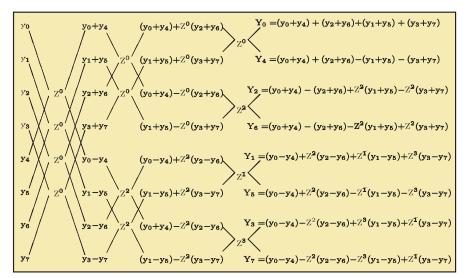

Now comes the real magic, and something that is used all over the place in fast, hardware-based calculations:

 \rightarrow notice the **repeating factors inside the parentheses**, they have the form $f_p \pm f_q$. These symmetries are systematized by introducing the **butterfly operation**.

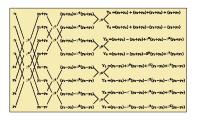

Butterfly calculations (II)

With the mapping $y \to f$, $Y \to \hat{f}$, this looks like a **network of complex additions and multiplications** for our N = 8 FFT:

Butterfly calculations (II)

With the mapping $y \to f$, $Y \to \hat{f}$, this looks like a **network of complex additions and multiplications** for our N=8 FFT:

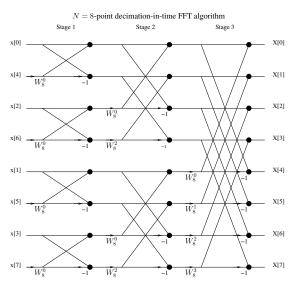

Notice how the number of multiplications of complex numbers has been reduced:

- For the first butterfly operation there are 8 multiplications by Z^0
- For the second butterfly operation there are 8 multiplications
- A total of 24 multiplications is made in four butterfly operations

Butterfly calculations (III)

This is often written in a slightly different form (notice anything?):

Danielson-Lanczos Lemma

The discrete Fourier transform of length N (where N is even) can be rewritten as the **sum of two discrete Fourier transforms**, each of length N/2, one for **even-numbered** points and the other for **odd-numbered** points.

$$\hat{f}_n = \frac{1}{\sqrt{2\pi}} \sum_{k=1}^{N} f_k Z_N^{nk}$$
 (7)

$$= \frac{1}{\sqrt{2\pi}} \sum_{k=1}^{N/2} f_{2k} Z_{N/2}^{nk} + Z_N^n \sum_{k=1}^{N/2} Z_{N/2}^{nk} f_{2k+1}$$
 (8)

$$= \hat{f}_n^{\text{even}} + Z_N^n \hat{f}_n^{\text{odd}}, \tag{9}$$

In fact, this procedure can be **applied recursively** to break up the N/2 even and odd points to their N/4 even and odd points.

If N is a power of 2, this procedure breaks up the original transform into $\ln N$ transforms of length 1.
